This sprint was setting the framework for the semester and making sure the scope was achievable, and communication from asset creation, mechanics, and environment art was all in line with the level and combat design. We have had many meetings this past week, going over the timeline and what the Environment artist needs from me as the level designer to make sure they have the time to get what we are calling stage 1 (the basic outline and shape with actual assets).

This week on the engineering side, I implemented the Prone player movement option to utilize more mechanics to navigate the environment and solve puzzles. This one was straightforward, but initially, I struggled with it, having to build it from scratch, as Unreal doesn't have a default prone ability as it does for crouch, but I realized that I could repurpose the Crouch functions to change how the hitboxes align.

For the design portion, I whiteboxed the first two puzzles, and formed a pipeline around our constraints based on work loads, scope, and time to complete for artist. The key principle was to design mechanics/solution of the puzzle to be independent of environment, or at least easily adaptable to changing environment design. The first puzzle was based on shooting targets that are blended with environment and the second puzzle (which was the focus of this sprint) was exploring a room to find a code and input it into a keypad to unlock an upgrade. Although the rooms were designed in a certain way, the main request from artist was to make it so we don't need to create to many new assets, and that we settled on two themes for rooms: a waiting room that looting rooms will be based on ,and storage room that puzzles will be based on.
(The glowing panels represent decals of numbers that players will look for

to get a code)
